

# Core Java

---

Java I/O & File Handling

# Lesson Objectives

- To understand the following topics:
  - Streams
  - Byte Stream I/O hierarchy
  - Character Streams: Readers and Writers
  - The File Class
  - Object Serialization

# Overview of I/O Streams

- Most programs need to access external data.
- Data is retrieved from an input source.
  - Program results are sent to output destination.

Figure 8-1: A program uses an input stream to read data from a source, one item at a time

Figure 8-2: A program uses an output stream to write data to a destination, one item at a time

# What is a Stream?

- Abstraction that consumes or produces information.
- Linked to source and destination.
- Java implements streams within class hierarchies defined in the *java.io* package.
- An *input* stream acts as a *source* of data.
- An *output* stream acts as a *destination* of data.

Figure 8-3: (a) Input Stream

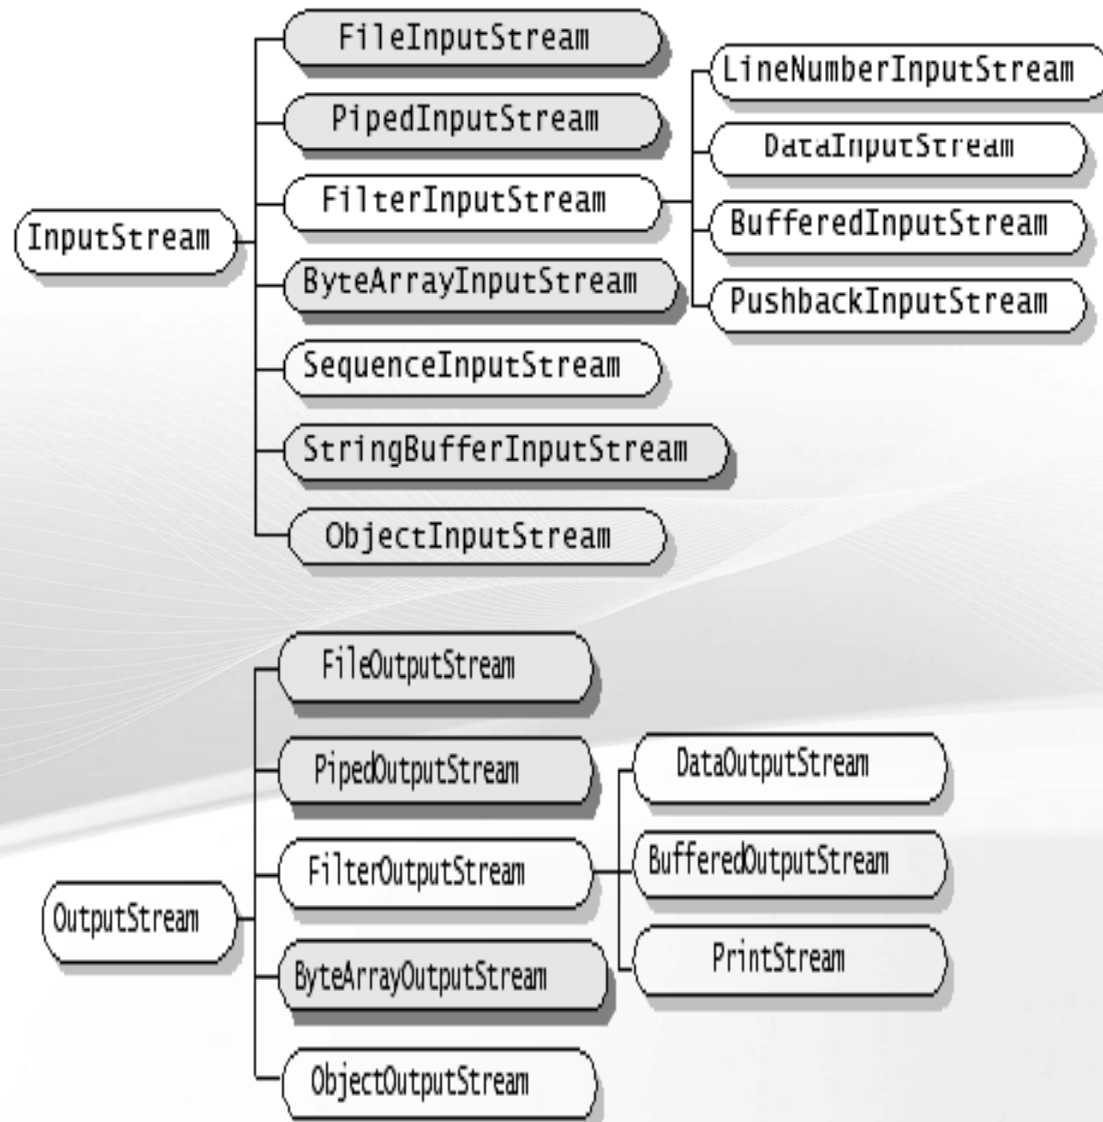

Figure 8-3:(b) Output stream

# Types of Streams

- *Byte Streams*: Handle I/O of raw binary data.
- *Character Streams*: Handle I/O of character data. Automatic translation handling to and from a local character.
- *Buffered Streams*: Optimize input and output with reduced number of calls to the native API.
- *Data Streams*: Handle binary I/O of primitive data type and String values.
- *Object Streams*: Handle binary I/O of objects.
- *Scanning and Formatting*: Allows a program to read and write formatted text.

# Byte Stream I/O Hierarchy

## InputStream Class - Methods

Method	Description
<code>close()</code>	Closes this input stream and releases any system resources associated with the stream.
<code>int read()</code>	Reads the next byte of data from the input stream.
<code>int read(byte[] b)</code>	Reads some number of bytes from the input stream and stores them into the buffer array <i>b</i> .
<code>int read(byte[] b, int off, int len)</code>	Reads up to <i>len</i> bytes of data from the input stream into an array of bytes.

## OutputStream Class - Methods

Method	Description
<code>close()</code>	Closes this output stream and releases any system resources associated with this stream.
<code>flush()</code>	Flushes this output stream and forces any buffered output bytes to be written out.
<code>write(byte[] b)</code>	Writes <i>b.length</i> bytes from the specified byte array to this output stream.
<code>write(byte[] b, int off, int len)</code>	Writes <i>len</i> bytes from the specified byte array starting at offset <i>off</i> to this output stream.
<code>write(int b)</code>	Writes the specified byte to this output stream.

# InputStream Subclasses

Classname	Description
<code>DataInputStream</code>	A filter that allows the binary representation of java primitive values to be read from an underlying inputstream
<code>BufferedInputStream</code>	A filter that buffers the bytes read from an underlying input stream. The buffer size can be specified optionally.
<code>FilterInputStream</code>	Superclass of all input stream filters. An input filter must be chained to an underlying inputstream.
<code>ByteArrayInputStream</code>	Data is read from a byte array that must be specified
<code>FileInputStream</code>	Data is read as bytes from a file. The file acting as the input stream can be specified by File object, or as a String
<code>PushBackInputStream</code>	A filter that allows bytes to be “unread “ from an underlying stream. The number of bytes to be unread can be optionally specified.
<code>ObjectInputStream</code>	Allows binary representation of java objects and java primitives to be read from a specified inputstream.
<code>PipedInputStream</code>	It reads many bytes from <code>PipedOutputStream</code> to which it must be connected.
<code>SequenceInputStream</code>	Allows bytes to be read sequentially from two or more input streams consecutively.

## FileInputStream and FileOutputStream Example

```
import java.io.*;
class CopyFile {
    FileInputStream fromFile;
    FileOutputStream toFile;
    public void init(String arg1, String arg2) {
        //Assign the files
        try{
            fromFile = new FileInputStream(arg1);
            toFile = new FileOutputStream(arg2);
        } catch (FileNotFoundException fnfe) {
            System.out.println("Exception: " + fnfe);
        } catch (IOException ioe) {
            System.out.println("Exception: " + ioe);
        } catch (ArrayIndexOutOfBoundsException aioe) {
            System.out.println("Exception: " + aioe);
        }
    }
}
```

## FileInputStream and FileOutputStream Example

```
public void copyContents() { // copy bytes
    try {
        int i = fromFile.read();
        while ( i != -1)
            { //check the end of file
                toFile.write(i);
                i = fromFile.read();
            }
    } catch (IOException ioe)
    { System.out.println("Exception: " + ioe);}
}
```

## FileInputStream and FileOutputStream Example

```
public void closeFiles() { //close the files
    try{
        fromFile.close();
        toFile.close();
    } catch (IOException ioe)
        { System.out.println("Exception: " + ioe);
    }
}

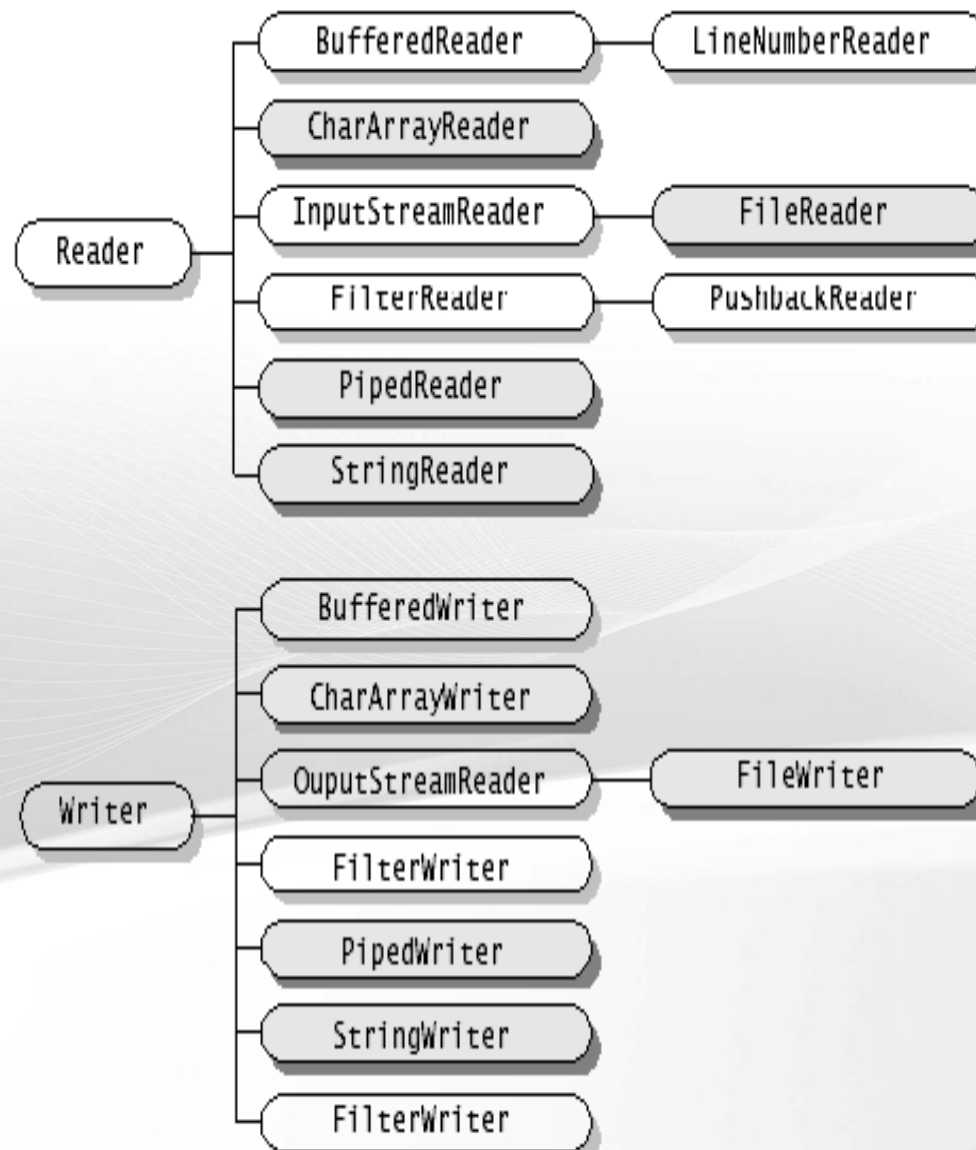

public static void main(String[] args){
    CopyFile c1 = new CopyFile();
    c1.init(args[0], args[1]);
    c1.copyContents();
    c1.closeFiles(); } }
```

**Demo:**

`CopyFile.java`

# Character Stream I/O Hierarchy

- All Character Stream classes are descended from *Reader* and *Writer* Abstract classes.
- Java represents characters internally in the 16-bit Unicode character encoding.
- *Reader* is an input character stream that reads a sequence of Unicode characters.
- *Writer* is an output character stream that writes a sequence of Unicode characters

Method	Description
<code>int read()</code> throws <code>IOException</code>	reads a byte and returns as an <code>int</code>
<code>int read(char b[])</code> throws <code>IOException</code>	reads into an array of chars <i>b</i>
<code>int read(char b[], int off, int len)</code> throws <code>IOException</code>	reads <i>len</i> number of characters into char array <i>b</i> , starting from offset <i>off</i>
<code>long skip(long n)</code> throws <code>IOException</code>	Can skip <i>n</i> characters.

## Writer Class - Methods

Method	Description
<code>void write(int c) throws IOException</code>	writes a byte.
<code>void write(char b[]) throws IOException</code>	writes from an array of chars <i>b</i>
<code>void write(char b[], int off, int len) throws IOException</code>	writes <i>len</i> number of characters from char array <i>b</i> , starting from offset <i>off</i>
<code>void write(String b, int off, int len) throws IOException</code>	writes <i>len</i> number of characters from string <i>b</i> , starting from offset <i>off</i>

## FileReader and FileWriter Example

```
import java.io.FileReader;
import java.io.FileWriter;
import java.io.IOException;
public class CopyCharacters {
    public static void main(String[] args) throws IOException {
        FileReader inputStream = null;
        FileWriter outputStream = null;
        try {
            inputStream = new FileReader("sampleinput.txt");
            outputStream = new FileWriter("sampleoutput.txt");
            int c;
            while ((c = inputStream.read()) != -1) {
                outputStream.write(c);
            }
        }
    }
}
```

## FileReader and FileWriter Example

```
} finally {  
    if (inputStream != null) {  
        inputStream.close();  
    }  
    if (outputStream != null)  
    {  
  
        outputStream.close();  
    }  
  
    }  
}
```

- An unbuffered I/O means each read or write request is handled directly by the underlying OS.
  - Makes a program less efficient.
    - Each such request often triggers disk access, network activity, or some other relatively expensive operation.
  - Java implements buffered I/O Streams to reduce this overhead.
    - Buffered input streams read data from a memory area known as a buffer; the native input API is called only when the buffer is empty.
    - Similarly, buffered output streams write data to a buffer, and the native output API is called only when the buffer is full.

# Buffered Stream

- A program can convert a un-buffered stream into buffered using the *wrapping idiom*:
  - Un-buffered stream object is passed to the constructor of a buffered stream class.
  - Example

```
InputStream =  
new BufferedReader(new FileReader("sampleinput.txt"));  
  
OutputStream =  
new BufferedWriter(new FileWriter("sampleoutput.txt"));
```

- Data Streams:

- Support binary I/O of primitive data type values:
  - boolean, char, byte, short, int, long, float, and double as well as String.
- All data streams implement either the *DataInput* interface or the *DataOutput* interface.
  - DataInputStream and DataOutputStream are most widely-used implementations.

## DataInputStream / DataOutputStream Methods

Read	Write	Type
<code>readBoolean</code>	<code>writeBoolean</code>	<code>boolean</code>
<code>readChar</code>	<code>writeChar</code>	<code>char</code>
<code>readByte</code>	<code>writeByte</code>	<code>byte</code>
<code>readShort</code>	<code>writeShort</code>	<code>short</code>
<code>readInt</code>	<code>writeInt</code>	<code>int</code>
<code>readLong</code>	<code>writeLong</code>	<code>long</code>
<code>readFloat</code>	<code>writeFloat</code>	<code>float</code>
<code>readDouble</code>	<code>writeDouble</code>	<code>double</code>
<code>readUTF</code>	<code>writeUTF</code>	<code>String</code> (in UTF format)

```
public static void writeData(double[] data, String file)throws
    IOException {
    OutputStream fout = new FileOutputStream(file);
    DataOutputStream out = new DataOutputStream(fout);
    out.writeInt(data.length);
    for (double d : data) {    out.writeDouble(d); }
    out.close();
}

public static double[] readData(String file) throws IOException {
    InputStream fin = new FileInputStream(file);
    DataInputStream in = new DataInputStream(fin);
    double[] data = new double[in.readInt()];
    for (int i = 0; i < data.length; i++) {    data[i] = in.readDouble(); }
    in.close();
    return data;
}
```

- Object streams support I/O of objects:
  - Support I/O of primitive data types.
  - Object has to be *Serializable* type.
  - *Object Classes*: ObjectInputStream, ObjectOutputStream
    - Implement ObjectInput and ObjectOutput, which are sub interfaces of DataInput and DataOutput.
  - An object stream can contain a mixture of primitive and object values.

- *Object Serialization:*

- Object Serialization allows an object to be transformed into a sequence of bytes that can be later re-created (deserialized) into an original object.
- Process to read and write objects.
- Provides ability to read or write a whole object to and from a raw byte stream.
- Use object serialization in the following ways:
  - *Remote Method Invocation (RMI)*: Communication between objects via sockets.
  - *Lightweight persistence*: Archival of an object for use in a later invocation of the same program.

## Object Serialization - Example

```
import java.io.*;
// This is a serializable object
class Employee implements Serializable {
    String name;
    int age;
    double salary;
    Employee(String name, int age, double salary) {
        this.name = name;
        this.age = age;
        this.salary = salary;
    }
    public void showDetails() {
        System.out.println("Name      :" + name);
        System.out.println("Age      :" + age);
        System.out.println("Salary   :" + salary);
    }
}
```

## Object Serialization - Example

```
class ObjectSerializationDemo {  
    void writeData() {  
        Employee db[] = {  
            new Employee("Sachin",25,12000.56),  
            new Employee("Rahul",24,12670.78),  
            new Employee("Hritik",28,16000.89)  
        };  
  
        try {  
            FileOutputStream out = new FileOutputStream("emp-obj.dat");  
            ObjectOutputStream sout = new ObjectOutputStream(out);  
            for (int i = 0; i < db.length ; i++ ) {  
                sout.writeObject(db[i]);  
            }  
            sout.close();  
        } catch (IOException ioe) {  
            ioe.printStackTrace();  
        }  
    }  
}
```

## Object Serialization - Example

```
    }  
    }  
    try  
    {  
        void readData() {  
            FileInputStream in = new FileInputStream("emp-obj.dat");  
            ObjectInputStream sin = new ObjectInputStream(in);  
            Employee e = (Employee) sin.readObject();  
            e.showDetails();  
            e = (Employee) sin.readObject();  
            e.showDetails();  
            e = (Employee) sin.readObject();  
            e.showDetails();  
            sin.close();  
        }  
    }  
}
```

```
    } catch (IOException ioe) {  
        ioe.printStackTrace();  
    } catch (ClassNotFoundException cnfe) {  
        cnfe.printStackTrace();  
    }  
}  
}  
public static void main(String args[]) {  
    ObjectSerializationDemo impl = new ObjectSerializationDemo();  
    impl.writeData();  
    impl.readData();  
}  
}
```

- **Demo:**  
ObjectSerializationDemo.java
